

Averaging Dive Scores

This program provides a tool that might be used to help judge a diving competition. The program asks the user to enter in a dive score from each of the three judges at the competition. These values are then passed as parameters to a method that calculates the average score. The average is returned to the Main() method where it is printed out.

In this program, we will also use a method to ask the user if they want to compute another average. This function will test the user's response to make certain that it is valid. It returns a boolean value that is equal to **true** when the user's response is "yes", and is equal to **false** when the user's response is "no".
